Frailty and dementia
Dementia is a progressive condition and over time, many people with the diagnosis experience physical frailty. This is particularly true for older people.

It is important to understand, recognise and manage frailty so that the person with dementia and their family can access the right care and support and have a better quality of life. For example, by identifying and addressing the causes of frailty, it may be possible to avoid unnecessary hospital admissions and enable people to be cared for in their own home for longer.

**What is frailty?**

Frailty is a long-term state of health that relates to a person’s physical and mental resilience. The physical characteristics of frailty are:

- weight loss
- poor nutrition
- hydration issues
- fatigue
- weakness
- reduced physical activity

- general slowing down

Frailty is a common condition and occurs in around 50% of people over the age of 85. Some people may experience frailty far earlier in life due to other physical or mental health issues, for example in young onset dementia (where symptoms develop before the age of 65). Often, people do not recognise themselves as frail.

People with frailty are unable to bounce back from even relatively minor injuries, illnesses or changes in their personal circumstances (for example a fall, infection, adjusting to a new medication, constipation, or urinary retention). As frailty increases, a person will steadily become more vulnerable, and this can have an increasingly negative impact on their health and independence.

**Stages of frailty**

There are three stages of frailty.

1. **Mild frailty**: the person may appear to be slowing down and need increasing help with everyday tasks such as meal preparation, managing finances,
3. Severe frailty: a person who is severely frail will be dependent on others for full assistance with all aspects of care.

A person’s level of frailty can change over time and may improve or worsen depending on what intervention, care and support they receive.

Understanding frailty syndromes

A syndrome is a group of characteristics, symptoms or conditions that typically go together. There are five frailty syndromes; if a person has one

2. Moderate frailty: a person with moderate frailty will need help with all outside activities and all elements of housekeeping. They often have significant difficulty with stairs and will require some assistance with bathing and dressing – this may be supervision, guidance or hands-on support.
usually referred to as Clinical Frailty Scores/Scales. These assess the person’s degree of fitness and frailty and classify it as mild, moderate or severe.

If you have concerns about frailty, the first step is to make an appointment with the GP. They may carry out an initial assessment themselves or refer the person to another professional or service for assessment.

Comprehensive Geriatric Assessment of frailty

If a person is identified as frail, they will typically receive a full assessment of their needs, known as a Comprehensive Geriatric Assessment (CGA). Despite its name, this assessment is also used for younger people with frailty.

A CGA is a review of the person’s current symptoms and signs of frailty, taking into consideration any underlying medical conditions. It is carried out by a professional or team of professionals with expertise in the care and management of frailty. The person with dementia and their family should be involved in all
assessment and planning around their frailty needs.

**What will be assessed?**

The CGA comprises:

- an assessment of the person’s overall health and wellbeing
- formulation of a care and support plan (CSP) to address any issues that are causing concern for the person and/or their family carers

It looks at the person’s signs, symptoms and needs in a number of different categories.

On p11, you will find a table that you can fill in before the CGA – this will ensure you go into the assessment feeling well prepared and give the assessor an overview of the person’s condition and needs.

**Functional capacity**

This assesses the person’s ability to perform everyday activities, taking into consideration factors such as their:

- mobility
- ability to communicate
- self-care
- self-direction, ie motivation
and ability to carry out tasks without assistance

- ability to work/work skills

**Falls risk**

This assesses:

- the person’s current level of falls risk
- how many falls or ‘near misses’ they have had
- their risk of sustaining a fall with an injury such as a broken bone or head injury
- what factors contribute to the person’s falls risk
- whether any of these risks can be modified or managed

**Cognition**

This assesses:

- the current challenges around the person’s cognition (thinking)
- their level of confusion
- their diagnosis of dementia
- the stage of dementia
- behaviours and psychological symptoms

**Mood**

This looks at any issues and/or concerns affecting the person’s general emotional and psychological wellbeing.

**Polypharmacy**

This refers to taking multiple medications and their effects. It may look at:

- any current medications that the person is taking
- how appropriate these are
- side effects
- contraindications of the medication prescribed
Frailty and dementia

• issues around medication administration (for example, whether the person remembers to take it)

Social support

This considers who supports the person living with dementia and whether the current level of support is sufficient, alongside a discussion of ways to enhance any support that is in place.

Financial concerns

This looks at the person’s eligibility for benefits and any other concerns regarding financial wellbeing.

Goals of care

This involves discussions around:

• the person and their family’s insight and understanding of their health and wellbeing
• wishes around goals of care and what is achievable
• planning for their future needs

Advance care preferences

This offers an opportunity to plan for the progression of the person’s condition and eventually, end-of-life care.

There may be additional assessments of:

Nutrition/weight

This assesses:

• whether the person is eating a varied diet with adequate fluid intake – if issues are identified, they may be referred to a dietitian
• their weight
• any changes in their eating habits and tastes
• their ability to swallow – they may be referred to a speech and language therapist if there are concerns

There may be a discussion regarding the person’s eating practices, such as times, routines, and processes, and whether items such as assistive cutlery could aid their independence. Please see Sources of support on p14 for our information on eating and drinking.

Urinary continence

This considers any concerns
around continence and the person’s ability to manage it. The person may be referred to continence services for an assessment of their needs and tailored provision of incontinence products.

**Sexual function**
This looks at the person’s sexual activity and any associated challenges. Please see Sources of support on p14-15 for our information on sex and intimacy and changes in sexual behaviour.

**Vision/hearing**
This assesses:
- any current or emerging concerns with the person’s vision and hearing
- any glasses or hearing aids that they need and use
- whether vision problems are contributing to the person’s falls risk

**Dentition**
This assesses oral health and denture use.

**Living situation**
This looks at the person’s current and future social care support needs and how to manage and mitigate any risks, for example by introducing assistive technology – please see Sources of support on p14-15 for our information on assistive living aids and making the home safe and comfortable for a person with dementia.

**Spirituality**
This considers the person’s spiritual, religious or cultural needs and wishes.

**Planning for the future**
Following a CGA, a care and support plan (CSP) should be formulated, focusing on:
- maintaining and optimising the health and functionality of the person living with frailty
- what to do if you or the person you support becomes unwell, including when you should seek help and who from
- making an ongoing care plan

Sometimes, frailty syndromes such as delirium, reduced
Frailty and dementia

Frailty is a long-term condition and typically worsens over time. However, some simple lifestyle changes may help a person with frailty function as well as possible.

- Look for ways to make the person’s home as safe and manageable as possible, e.g., removing trip hazards – you can ask social services for a needs assessment and home assessment to identify improvements or adaptations that may help. Please see Sources of support on p15 for information.

- Make sure the person has regular health checks including blood pressure, hearing and sight tests to identify any problems that could lead to falls.

- Support the person to eat a healthy, balanced diet and to stay well hydrated – this will...
help their overall health and reduce the risk of issues such as constipation and urinary tract infections (UTIs) that can affect continence

• Encourage the person to stay mobile and if possible, take exercise, as this builds bone and muscle strength. Seated exercises can be beneficial for people with frailty

• Ensure the person takes any medication as prescribed and attends regular medication reviews

• Make sure the person sees their GP if there are signs of illness, infection, pain or delirium

Preparing for a Comprehensive Geriatric Assessment

Use the following table to write down your concerns in each of the CGA areas to share with the professionals conducting the assessment.

If you are completing the table on behalf of the person you support, remember to also think about your own needs as a carer – if you do not look after your own health and wellbeing, you will be less able to care for the person with dementia.
